Project Report

on

Predictive Healthcare System Using Machine Learning for Early Diagnosis

submitted as partial fulfillment for the award of

BACHELOR OF TECHNOLOGY DEGREE

SESSION 2024-25

in

Name of discipline

By

Ayushi Pal (2200291520090)

Ishika (2200291520090)

Pari Agarwal (2200291520122)

Under the supervision of

Ms. Akansha

KIET Group of Institutions, Ghaziabad

Affiliated to

Dr. A.P.J. Abdul Kalam Technical University, Lucknow

(Formerly UPTU)

May, 2025

DECLARATION

We hereby declare that this submission is our own work and that, to the best of our knowledge and belief, it contains no material previously published or written by another person nor material which to a substantial extent has been accepted for the award of any other degree or diploma of the university or other institute of higher learning, except where due acknowledgment has been made in the text.

Date:

CERTIFICATE

This is to certify that Project Report entitled "Predictive Healthcare System Using Machine Learning for Early Diagnosis" which is submitted by Student name in partial fulfillment of the requirement for the award of degree B. Tech. in Department of CSE (AI) of Dr. A.P.J. Abdul Kalam Technical University, Lucknow is a record of the candidates own work carried out by them under my supervision. The matter embodied in this report is original and has not been submitted for the award of any other degree.

Supervisor Name **Dr. Rekha Kashyap**

(Designation) **Dean – CSE (AI/AI&ML)**

Date:

ACKNOWLEDGEMENT

It gives us a great sense of pleasure to present the report of the B. Tech Project undertaken during B. Tech. Final Year. We owe special debt of gratitude to superisor name, Department of CSE(AI), KIET, Ghaziabad, for his constant support and guidance throughout the course of our work. His sincerity, thoroughness and perseverance have been a constant source of inspiration for us. It is only his cognizant efforts that our endeavors have seen light of the day.

We also take the opportunity to acknowledge the contribution of Dr. Rekha Kashyap, Dean of the Department of Computer Science & Engineering (AI/AI&ML), KIET, Ghaziabad, for his full support and assistance during the development of the project. We also do not like to miss the opportunity to acknowledge the contribution of all the faculty members of the department for their kind assistance and cooperation during the development of our project.

We also do not like to miss the opportunity to acknowledge the contribution of all faculty members, especially faculty/industry person/any person, of the department for their kind assistance and cooperation during the development of our project. Last but not the least, we acknowledge our friends for their contribution in the completion of the project.

ABSTRACT

This electronic document focuses on machine learn ing to predict diseases such as pneumonia, breast cancer and heart diseases. The model analyzes a range of datasets and algorithms to provide accurate, early-stage predictions that can help in medical diagnosis and planning of the treatment. The system makes use of different medical datasets and applies suitable algorithms to identify complex patterns in less amount of time. By analyzing the patient information, the model can give an early indication of whether a person is at risk of a certain disease or having no disease. This technique of models can also support the doctors to make faster and more accurate decisions during diagnosis and treatment with higher accuracy and consistent results. After analyzing the clinical and health results, patients are categorized into disease prone or non disease prone. The purpose of this model is to improve health efficiency, basically in those environment where the resources related to medical are limited. This can only be done by analyzing the complex patterns of the patient data in less amount of time. It includes various medical datasets and multiple algorithms to generate reliable and efficient early stage prediction. With the help of continuous training and improvement of the model, reliable and accurate results are obtained across diverse patient records. Feature extraction and selection techniques are applied so that only the most significant medical indicators are analyzed. A user friendly design has also been designed so that the system can be accessed in both rural and urban healthcare environments where expert resources are limited. The other important objectives of the model are minimizing manual effort, reducing delays, offering early disease prediction, and a medical recommendation. The enhancement of the accuracy of prediction will help in making better decisions during treatment planning effectively. Index Terms—Breast cancer, Heart diseases, Pneumonia, Dis ease prediction, Machine learning, Healthcare system.

CHAPTER 1
INTRODUCTION

1.1 INTRODUCTION

Accurate prediction of a disease in time has come to be regarded as an essential aspect of health care provision. This paper discusses the diseases affecting a significant portion of the population, including pneumonia, breast cancer, thyroid disorders, and heart disease. The contribution of this research effort is essentially the designing of a trustworthy intelligent system that assists health practitioners in offering diagnosis suggestions based on patient data. This will enable early identification of diseases, making treatment easier and more focused, enhancing patient outcomes, and reducing general health costs.

Many observations indicate that machine learning algo rithms can detect serious diseases before they reach a critical stage. Diseases like breast cancer, heart disease, pneumonia, and disorders of the thyroid continue to be some of the major causes of mortality in many countries; however, emerging approaches have shown that techniques involving machine learning and artificial intelligence can make earlier prediction and proper intervention for patients affected by such conditions feasible.

Despite these advances, most of the conventional diagnostic procedures involve manual examination and interpretation. These methods are prone to human error and take up a great deal of time; furthermore, their results may be inconsistent for different practitioners. The goal of this project is to enable the prediction of multiple diseases by analyzing information related to patients, such as symptoms, past history, and labora tory reports. The platform is designed to yield accurate results based on advanced algorithms and processes that involve data collection, feature selection, cleaning of

data, and training of the model. Most importantly, the delivery of results has been ensured in a clear and concise manner to help in accurate clinical decision-making.

1.2 PROJECT DESCRIPTION

The Predictive Healthcare System using Machine Learning is a web-based application designed to predict different diseases at an early stage using patient data. The system uses machine learning algorithms to analyze medical datasets and identify patterns related to diseases. In this project, diseases such as heart disease, breast cancer, pneumonia, and thyroid disorders are predicted using various machine learning models. These models include Logistic Regression, Decision Tree, Random Forest, and Support Vector Machine (SVM).

The system works by collecting user inputs such as symptoms, medical test results, and other health-related information. This data is then processed using data preprocessing techniques such as cleaning, normalization, and feature selection. After preprocessing, the machine learning models analyze the data and generate predictions about whether the patient is likely to have a specific disease. Overall, this project demonstrates how machine learning can be effectively used in the healthcare sector to improve diagnosis, enhance decision-making, and provide better medical support in environments where medical resources may be limited.

CHAPTER 2

LITERATURE REVIEW

Recently, investigations have focused more on data-driven and artificial intelligence methods in the early detection and diagnosis of diseases. Discussions in the literature [1] refer to the use of several algorithms for the early detection of cardio vascular diseases, focusing on how such predictions should be timely and exact, and independent of manual diagnostic procedures. On the same line of interest, other works [2] underline the rising importance of machine learning algorithms in medical diagnostics, presenting both a practical overview of the commonly used techniques and their effectiveness in predicting diseases. An assessment of breast cancer diagnostic practices was carried out in [3]. It shows that maintaining the structur quality assurance standards can easily enhances the accuracy as ompared to the achieved through traditional mammography only. In [4], different artificial intelligence techniques are applied to observe the results. After this research, it states that artifical intelligence techniques are not only capable of predicting the diseases but also capable of understanding the complex patterns. In [5], mammographic images and patient records were analyzed using deep learning approaches for breast cancer prediction. This work shows that both images and the provided patient data can predict the disease in easy way. A novel linear regressive classifier for breast cancer de tection is proposed in [6], which reportedly delivers more consistent and reliable results than previous models. For breast cancer classification, machine learning algorithms were assessed in [7]. It is found that the choice of algorithms and the data preprocessing truly plays an important role to achieve high accuracy. Deep learning developments are also reflected in [8], where a neural network framework for thoracic disease prediction from chest X-rays demonstrates significant gains across a wide range of conditions. In ophthalmology [9], discusses the development of a deep learning model for diabetic retinopathy diagnosis that attained diagnostic performance on par with expert ophthalmologists and demonstrated great potential for automated screening tools. Taken all together, these studies demonstrate an increasing role for AI and machine learning in diagnosis, streamlining clinical workflows, and driving data-informed decisions in healthcare. In [10], the full description of the methods that are used for predicting heart disease is mentioned. The authors states that the accuracy of the

chosen models is mainly depend on the relevance of clinical features, quality of dataset and design of the model. In [11], a heart disease prediction system based on the concept of machine learning is introduced. According to this report, using structured clinical attributes plays a significant role in improving the prediction accuracy. Machine learning is validated for detecting pneumonia from chest X-rays in [12], where image-based diagnosis can alleviate the clinical workload and enable early intervention. The correct and exact use of artificial intelligence in var ious healthcare sectors is reviewed in [13]. It discusses the transformative potential of AI-based tools in healthcare, with emphasis on patient monitoring, diagnostics, and decision support systems. Although not focused on medical data, a hybrid CNN–SVM model for handwritten digit recognition was presented in [14]. The effectiveness of combining deep learning with traditional learning methods indicates that such hybrid approaches may also be valuable for medical imaging tasks.

Finally, [15] investigated thyroid disease prediction us ing machine learning algorithms. The study observed that performance strongly depends on appropriate preprocessing, normalization, and selecting the most relevant features. Taken all together, these studies demonstrate an increasing role for AI and machine learning in diagnosis, streamlining clinical workflows, and driving data-informed decisions in healthcare.

CHAPTER 3

PROPOSED METHODOLOGY

A. Data Collection

We used publicly accessible datasets, one dataset focused on diabetes cases, another containing breast cancer. This type of datasets provides the current condition of the patient and helps in the training and evaluation of models.

B. Data Preprocessing

Uses some data preprocessing techniques like handling missing values, normalization, feature selection on using cor relation and label encoding for categorical variables.

C. Algorithms Used

We used some algorithms like Logistic Regression for binary classification problems, decision trees for easy use, random forest for improving the accuracy.

D. System Architecture

The architecture of this disease prediction system contains modules that are designed to ensure accurate, efficient, and secure predictions

E. User Input Layer

The User Input Layer acts as an interface where user can input their symptoms, medical test reports.An interface with user friendly format helps them to enter their details in a simple format.

F. Data Preprocessing Module

Once the inputs are entered by the user, these are collected followed by cleaning and standardization of data using several techniques like handling missing values,

normalization or standardization to ensure uniform scaling, label encoding to convert categorical attributes into numerical form.

Feature Selection using correlation matrices and statistical f ilters to eliminate irrelevant attributes. This module ensures data quality, which is crucial for accurate predictions.

G. Feature Engineering Layer

This layer extracts the meaningful features that improves the performance of our model. It includes terms like dimensional ity reduction (PCA, feature ranking). Domain-specific feature extraction from clinical indicators. Construction of derived metrics (risk scores, ratio-based features)

H. Machine Learning Models

This is the core analytical module that applies trained ma chine learning models to processed data. It includes terms like logistic regression for baseline binary detection, decision tree classifier for high interpretability, random forest for reducing overfitting and increasing accuracy, support vector machine (SVM) for handling high-dimensional decision boundaries of the data.

The module outputs the following things like probabilities of disease occurrence, final classification decision, model con f idence levels, ensemble predictions may be used to improve robustness.

CHAPTER 4

RESULTS AND DISCUSSION

The results of the proposed disease prediction system were evaluated using different machine learning algorithms such as Logistic Regression, Decision Tree, Random Forest, and Support Vector Machine (SVM). These models were trained and tested on medical datasets related to diseases such as heart disease, breast cancer, pneumonia, and thyroid disorders. The performance of each model was measured using evaluation metrics like accuracy, precision, recall, and F1-score**.**

For the heart disease dataset, the Random Forest algorithm achieved the highest accuracy of 88%**,** while SVM achieved 85%**,** Decision Tree achieved 82%, and Logistic Regression achieved 72%**.** This shows that ensemble methods like Random Forest perform better because they combine multiple decision trees and reduce overfitting.

In the breast cancer dataset, the machine learning models showed very high prediction accuracy. The SVM model achieved the best performance with accuracy above 97% in some dataset splits, while Logistic Regression and Random Forest also produced very reliable results. These results show that machine learning algorithms are highly effective for detecting breast cancer from clinical data.

For pneumonia detection, the models were tested using different training and testing data splits. The SVM model again performed well with accuracy close to **96%**, while Logistic Regression and Random Forest also achieved strong results above **94%**. This indicates that the models can successfully detect pneumonia cases from the dataset.

The results clearly show that machine learning techniques can effectively predict diseases with high accuracy when proper preprocessing and feature selection techniques are used. Among all the models, Random Forest and SVM performed better compared to other algorithms because they can handle complex data patterns more efficiently.

Overall, the experimental results demonstrate that the proposed system can assist healthcare professionals by providing quick and reliable disease predictions. This can help in early diagnosis, better treatment planning, and reducing the workload of medical experts.

CHAPTER 5

CONCLUSION AND FUTURE SCOPE

The results of our project shows that machine learning is capable of significantly help us to increase the accuracy and efficiency of disease prediction model. With the use of various algos—including logistic regression, decision tree, random for est, and SVM—it has been shown that dependable predictive outputs are produced to support health related profession for early diagnosis of diseases and preventive decision-making. Among all the models which are examined, the random forest classifier was found to help in deliver the maximum accuracy along with better stability and generalization, indicating its suitability for practical clinical environments. The study also highlights that careful data preprocessing, meaningful feature selection, and the use of ensemble-based strategies are essen tial for achieving consistent and strong predictive performance. Overall, it is observed that machine learning–driven techniques hold considerable promise for healthcare settings by enabling earlier detection and reducing the burden associated with manual diagnostic procedures.

APPENDIX 1

Appendix A: Dataset Description

The datasets used in this project were collected from publicly available medical repositories such as Kaggle and UCI Machine .

1.Heart diseases

2. Breast Cancer

3.Thyroid

4.Pnemomia

Appendix B: Data Preprocessing Steps

1. Handling missing values using mean/median imputation
2. Encoding categorical variables using Label Encoding
3. Feature scaling using StandardScaler
4. Splitting dataset into training and testing sets (80:20 ratio)

Appendix C: Machine Learning Algorithms Used

The following algorithms were implemented:

Logistic Regression , Decision Tree, Random Forst Classifier, Support Vector Machine, K-Nearest Neighbour.

Appendix D: Evaluation Metrics

To evaluate model performance, the following metrics were used:

Accuracy, Precision, recall, confusion metric, error.
